# predict-iris-species

Sulaksh Swami

August 17, 2021

# **Synopsis**

This predictive modeling project aims to build a machine learning model to predict the species of iris based on 4 numeric features. The data comes from the iris dataset built into R.

## Setup

Import the libraries needed for the project.

```
library(e1071)
library(naniar)
library(ggplot2)
library(GGally)

Registered S3 method overwritten by 'GGally':
    method from
    +.gg    ggplot2

library(tidyr)
library(corrplot)

corrplot 0.89 loaded

library(caret)

Loading required package: lattice
```

### **Load the Data**

Load the data.

```
data(iris)
```

Store the data in a data frame.

```
df <- iris
```

#### **Describe the Data**

Look at the head and tail of the data.

```
head(df)
```

```
Sepal.Length Sepal.Width Petal.Length Petal.Width Species

       Species
 setosa
           :50
 versicolor:50
 virginica:50
```

Obtain the standard deviations of the numeric variables. All variables are numeric here.

```
X <- df[, colnames(df) != "Species"]
sapply(X, sd)
Sepal.Length Sepal.Width Petal.Length Petal.Width
     0.8280661     0.4358663     1.7652982     0.7622377</pre>
```

Obtain the distribution of instances across different class labels.

Obtain the correlations between the numeric variables.

```
cor(X)
           Sepal.Length Sepal.Width Petal.Length Petal.Width
Sepal.Length 1.0000000 -0.1175698
                                     0.8717538
                                                0.8179411
                                    -0.4284401 -0.3661259
Sepal.Width
             -0.1175698 1.0000000
Petal.Length
              0.8717538 -0.4284401
                                    1.0000000
                                                0.9628654
Petal.Width
              0.8179411 -0.3661259
                                    0.9628654
                                               1.0000000
```

Obtain the skew of each numeric variable in the data.

```
sapply(X, skewness)
Sepal.Length Sepal.Width Petal.Length Petal.Width
   0.3086407   0.3126147  -0.2694109  -0.1009166
```

Use the Shapiro-Wilk test to check if the numeric variables in the data are Gaussian.

	p.values	is.gaussian
Sepal.Length	1.018116e-02	FALSE
Sepal.Width	1.011543e-01	TRUE
Petal.Length	7.412263e-10	FALSE
Petal.Width	1.680465e-08	FALSE

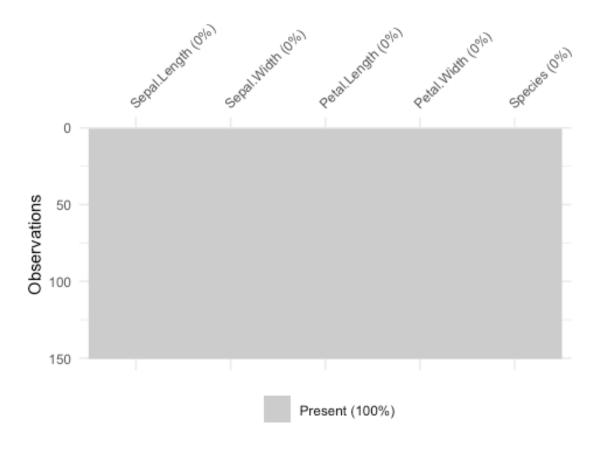

The output indicates that only Sepal. Width is Gaussian at a 0.05 significance level. Keeping this in mind, I pick the XGBoost algorithm for modeling the problem, since this algorithm doesn't assume that its features are Gaussian.

### **Visualize the Data**

#### **Univariate Plots**

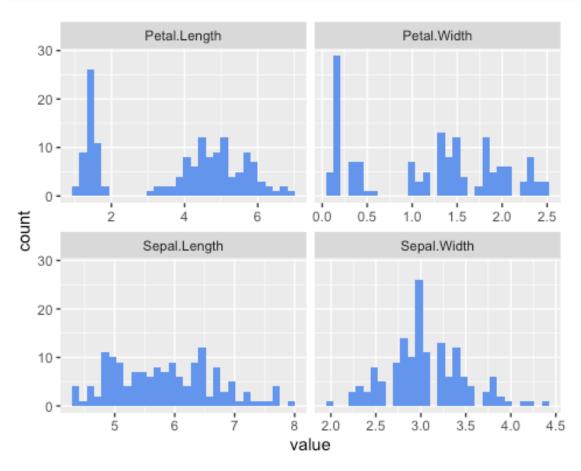

Make a missing value plot to diagnose the presence of missing values in the data.

## vis\_miss(df)

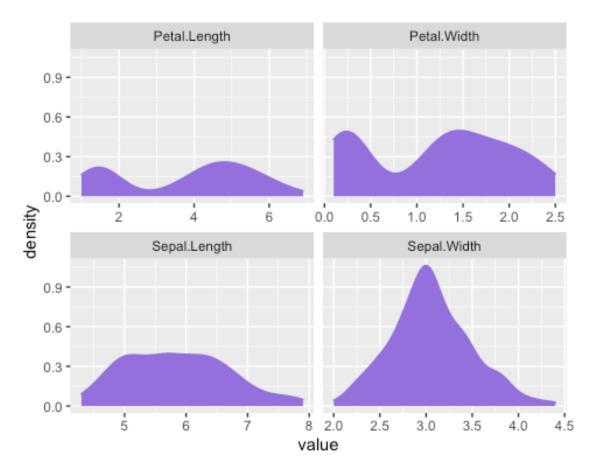

The plot's output indicates that no variable has missing values. Hence, no imputation will have to be carried out during preprocessing.

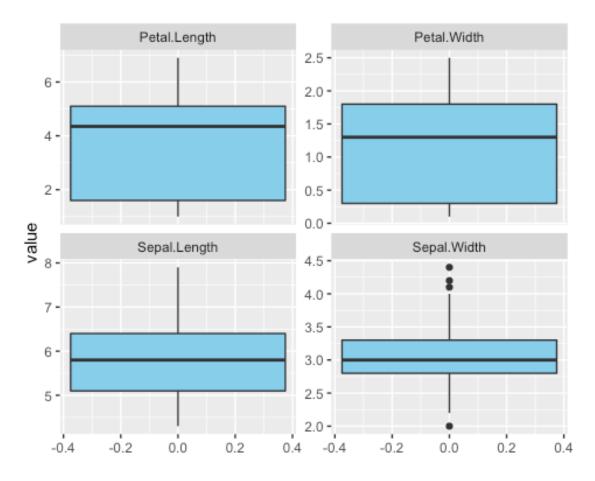

Make a histogram for each numeric variable.

Make a density plot for each variable.

Make a boxplot for each variable.

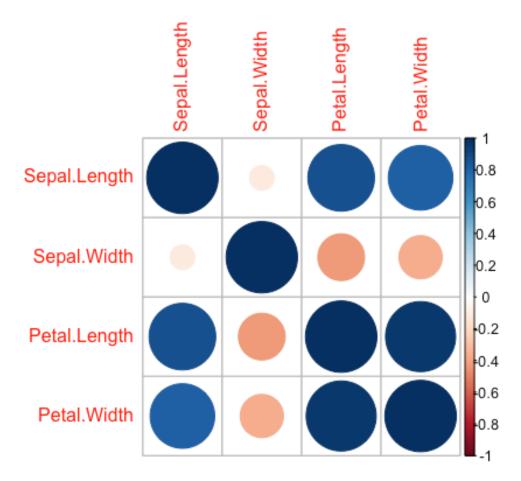

## **Multivariate Plots**

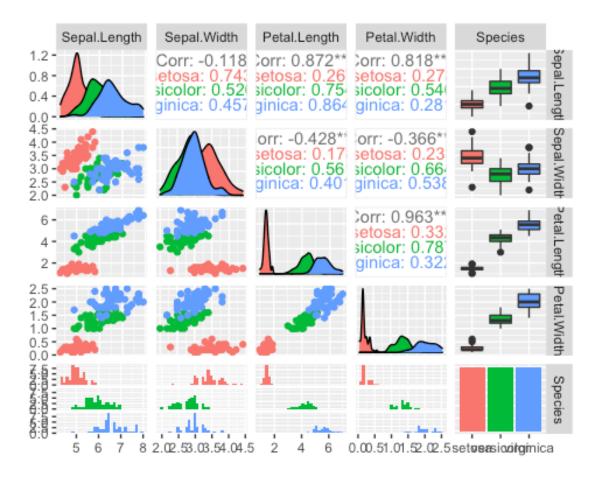

Make a correlation matrix plot to visualize the correlation between the numeric variables in the data.

```
correlations <- cor(X)

corrplot(correlations,
    method = "circle")</pre>
```

Make a scatter plot matrix for the data frame.

## **Data Partitioning**

Data partitioning of the data frame into the features and the target variable has already been done.

```
str(X)
'data.frame': 150 obs. of 4 variables:
   $ Sepal.Length: num 5.1 4.9 4.7 4.6 5 5.4 4.6 5 4.4 4.9 ...
   $ Sepal.Width : num 3.5 3 3.2 3.1 3.6 3.9 3.4 3.4 2.9 3.1 ...
   $ Petal.Length: num 1.4 1.4 1.3 1.5 1.4 1.7 1.4 1.5 1.4 1.5 ...
   $ Petal.Width : num 0.2 0.2 0.2 0.2 0.4 0.3 0.2 0.2 0.1 ...
str(y)
Factor w/ 3 levels "setosa", "versicolor", ..: 1 1 1 1 1 1 1 1 1 1 ...
```

# **Preprocessing**

All variables are numeric. The data needs to be scaled to a mean of 0 and a standard deviation of 1. Preprocessing will be carried out during training.

#### **Tune the Model Parameters**

Make a grid of candidate parameters.

Set up cross-validation.

Train the model using the grid search harness.

```
model \leftarrow train(x = X,
               y = y
               method = "xgbTree",
               preProcess = c("center", "scale"),
               metric = "Accuracy",
               maximize = TRUE,
               trControl = train.control,
               tuneGrid = tune.grid)
model

parameter 'gamma' was held constant at a value of 0
```

```
Tuning parameter 'nrounds' was held constant at a value of 100
Tuning
```

Tuning

parameter 'min\_child\_weight' was held constant at a value of 0 Accuracy was used to select the optimal model using the largest value. The final values used for the model were nrounds = 100, max depth = 4, eta = 0.02, gamma = 0, colsample bytree = 0.6, min\_child\_weight = 0 and subsample = 0.75.

ggplot(data = model)

```
print("The best parameters obtained from the grid search are:")
[1] "The best parameters obtained from the grid search are:"
print(model$bestTune)
  nrounds max_depth eta gamma colsample_bytree min_child_weight subsample

best.accuracy.standard.error <- model$results[best.row, ]$AccuracySD</pre>
cat("The accuracy score obtained for the best parameters is", best.accuracy,
"with a standard error of", best.accuracy.standard.error)
The accuracy score obtained for the best parameters is 0.96 with a standard
error of 0.02788867
```

Store the final model as a fit object.

final.model <- model\$finalModel</pre>

## **Save the Model**

Save the model to disk so that it may be conveniently loaded later, as and when it is required to make predictions on iris data.
